Citation: Gregory Russell-Jones. Functional Vitamin B2 Deficiency in Autism. *Journal of Pediatrics, Perinatology and Child Health* 6 (2022): 305-313.

Abstract

Functional vitamin B2 levels were assessed in 600 children with autism aged between two and 30 years old. Every child assessed was found to have functional vitamin B2 deficiency. The deficiency appears to have stemmed from deficiencies in Iodine, Selenium and/or Molybdenum as was found in a previous report by this lab. Functional vitamin B2 is a known essential co-factor in the maintenance of the activity of vitamin B12, and potentially this would also mean that each child was deficient in functional vitamin B12 – a known predisposing factor for autism.

Keywords: Autism; Organic Acids Test; Vitamin B2; Riboflavin

1. Introduction

Riboflavin, also known as vitamin B2, is known to play an essential role in health and metabolism. In order to do this, however, riboflavin must first be modified (activated) within the body. The activation of dietary or supplemental riboflavin involves contribution from Thyroid Stimulating Hormone (TSH), which stimulates the uptake of Iodine into the thyroid gland to make thyroid hormone (tetraiodothyronine, T4). T4 is in turn activated by removal of one Iodine to form T3 (triiodothyronine) by the Selenoprotein, iodothyronine deiodinase. T3 is then used in turning on the production of the first enzyme involved in riboflavin modification, riboflavin kinase. The resultant molecule, flavin mononucleotide (FMN), is further modified by the Molybdopterin-protein, FAD synthase, to form FAD. Hence, all three of Iodine, Selenium

and Molybdenum are required for the complete activation of vitamin B2 to FMN and FAD. The activated FMN and FAD are used as co-factors in over 100 “flavoproteins” in the body. Several of these flavoproteins have important roles in the body in the activation of several vitamins, or in the maintenance of vitamin activity. Hence, FMN is a co-factor in the enzyme pyridoxine 5-phosphate oxidase, which converts pyridoxal to pyridoxal-phosphate, the active form of vitamin B6. FMN and FAD work together in several enzymes, including methionine synthase reductase (MTRR), a rescue enzyme in methyl B12 metabolism. FAD is also involved in the activity of methylenetetrahydrofolate reductase (MTHR), an enzyme that is responsible for converting 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate (5MTHF).

Vitamin B2, as FAD, is an essential co-factor for long, medium and short chain acylCoA-dehydrogenase [1, 2], and as such has a critical role in fat metabolism. Insufficient FAD in the womb, leads to a reduced capacity of the foetus, neonate or child to metabolize fat for energy, and can lead to many conditions including failure to thrive, metabolic acidosis, ketotic hypoglycemia, lethargy, hypotonia, developmental delay, seizure, myopathy and dystonia. FAD also is involved in a complex co-enzyme complex within pyruvate dehydrogenase interacting with thiamine-pyrophosphate (TPP) and alpha-lipoic acid (ALA), plus nicotinamide adenine dinucleotide and acetyl-CoA. Pyruvate dehydrogenase is effectively the last enzyme in glycolysis and lack of FAD reduces the conversion of pyruvate to acetyl-CoA. This then leads to the isomeric conversion of pyruvate to lactate, with the subsequent build-up of lactic acid. Genetic mutations in pyruvate dehydrogenase have been associated with elevated levels of lactic acid in serum, and a

syndrome of neurologic signs, including hypotonia, epilepsy, metabolic abnormalities and microcephaly. Developmental delay is a nearly universal consequence of the condition [3]. FMN is also an essential co-factor for the citric acid cycle enzyme succinate dehydrogenase/respiratory complex II. The major enzyme that “bridges” Krebs cycle and the Electron Transport Chain. FMN, through its’ role in the activation of vitamin B6, is also required for the formation of Serotonin from 5-hydroxytryptophan by the P5P-dependent enzyme, hydroxytryptophan decarboxylase.

In the study reported here, Organic Acids Test data obtained from children with a diagnosis of Autism Spectrum Disorder (ASD) has been used to ascertain if there is an alteration in the accumulation of various markers associated with functional B2 deficiency, including glutaric acid, fatty acids, lactic acid, Quinolinic Acid:Kynurenic Acid, and oxalic acid, in these individuals.

2. Methods

2.1 Study sample

Data analysis was carried out under the Australian National Health and Medical Research Council guidelines (NHMRC). Under these guidelines, all data was deidentified and steps were taken to ensure the anonymity and confidentiality of the data. Deidentification has consisted of absolute anonymity and confidentiality of the data, such that no specifics such as gender, ethnicity, Country of Origin, etc is associated with any data point in the study. As such per the NHMRC guidelines:

1. The research does not carry any risk to the participants.

2. The benefits of the research are many and will be of considerable benefit to any past, current or future participants, and as such represent no harm.
3. The data is from over 600 participants collected over 6 years and as such it would be impracticable to obtain consent from the participants. Further the participants had been notified at the time of analysis that data presented for analysis might potentially be used in research – but would be totally de-identified (which it has been).
4. There is no known reason why any of the participants would not have consented if they had been asked.
5. Given the total de-identification of the data, there is absolute protection of their privacy.
6. Data is only housed in one location and has only been assessed by one person, and as such the confidentiality of the data can be assured.
7. No financial benefits from the data is anticipated, rather the data will be used to help prevent and treat those to whom the data applies.
8. The waiver is not prohibited by State, Federal or International Law.

A retrospective analysis was performed upon data submitted to us for analysis from a cohort of 600 children and adults who had been diagnosed with ASD from countries including USA, Canada, United Kingdom, Ireland, Germany, Spain, France, Italy, Bulgaria, India, Sweden, Bulgaria, Serbia, Dubai, Croatia and Australia. Age distribution of the 600 individuals was 1-5 (358); 6-10 (172); 11-15 (46); 16-20 (9); >21 (16). No selection was made in the acceptance of data, with

no data being rejected. We were not made privy to either the methods of assessment nor of the severity of the Developmental Delay in the Children. Data is presented regardless of sex, or age. Ages varied from 1 year old to thirty-four years old. Organic Acid Test Data (600 sets, Great Plains Laboratories, Lenexa, KS, USA), which had been submitted to us for interpretation, by parents of children with autism spectrum disorder, (ASD) was compared to that from persons who were healthy, and who had no previously identified health condition (NT). Individual data is plotted as Scattergrams (see Graphs 1 to 3). Organic Acid Test Data (OAT) (600 sets, Great Plains Laboratories, Lenexa, KS, USA), from children with ASD, was compared to that from persons who were healthy, and who had no previously identified health condition, and was plotted as Scattergrams (see Graphs 1 to 8). Data is represented as mmol/mol creatine for NT (n=20), and ASD (n=600)

3. Results

Analysis of OAT data from 600 children diagnosed with ASD revealed each and every child had a functional deficiency in vitamin B2 (see Figures 1 to 4), as defined by elevation in levels of Organic Acids. Thus, there was reduced activity of acyl-CoA-reductase (Figures 1, 2), leading to elevations in Ethylmalonic acid, Methylsuccinic acid, adipic acid and suberic acid, as well as reduced activity of the FAD-dependent enzyme, Glutaryl-CoA reductase, leading to elevated glutaric acid (Figure 3). In addition, there was reduced activity of the FAD/TPP/lipoate-dependent enzyme pyruvate dehydrogenase, leading to elevated lactic acid (Figure 4 Left Panel). These large elevations in organic acids, reflect energy loss from the metabolism of fats and sugars, and as a result in order to obtain sufficient energy, the ASD

individuals revert to the catabolism of proteins, yielding glucogenic and ketogenic amino acids. Part of this catabolism is the metabolism of hydroxyproline, to yield glyoxylate, which is then converted to Glycolate via the FAD-dependent enzyme, glyoxylate reductase. In FAD-deficiency, however, glyoxylate is oxidized to yield oxalic acid, via lactate dehydrogenase and glyoxylate oxidase. In concordance with the elevations in other FAD-deficiency markers, levels of oxalic acid were elevated in persons with ASD

(Figure 4. Right Panel). Conversion of kynurenin to kynurenic acid is dependent upon the vitamin B6 dependent enzyme kynurenin amino transferase, and in functional FMN deficiency, there is reduced production of the active form of vitamin B6, P5P, resulting in an increased ratio of QA:KA (Table 1). The degree of functional B2 deficiency was highly variable between ASD individuals as is reflected in the high standard deviation from the mean values (Table 1)

Figure 1: Ethylmalonic acid (Left Panel) and Methylsuccinic acid (Right Panel) in the urine of neurotypical (NT) and individuals with autism (ASD).

Figure 2: Suberic acid (Left Panel) and Adipic acid (Right Panel) in the urine of neurotypical (NT) and individuals with autism (ASD).

Figure 3: Glutaric acid (Left Panel) and Succinic acid (Right Panel) in the urine of neurotypical (NT) and individuals with autism (ASD).

Figure 4: Lactic acid (Left Panel) and Oxalic acid (Right Panel) in the urine of neurotypical (NT) and individuals with autism (ASD).

Marker	NT	ASD
Ethyl Malonic Acid	1.53 +/- 1.12	3.10 ± 2.3
Methyl Succinic Acid	1.25 ± 1.02	3.11 ± 3.1
Adipic Acid	1.45 ± 1.2	7.12 ± 15.2
Suberic Acid	1.77 ± 2.29	6.0 ± 11.9
Lactate	12.9 ± 15.6	29.1 ± 40.28
QA:KA	3.12 ± 2.05	5.32 ± 12.89
Succinate	4.48 ± 3.14	28.5 ± 44.8
Glutarate	0.27 ± 0.24	1.25 ± 1.77
Oxalate	71.73 ± 50.6	269 ± 231

4. Discussion

In a previous article [4] it was found that all children with ASD that were tested were deficient in one of more of Iodine, Selenium and Molybdenum, each of which is involved in the activation of vitamin B2 (riboflavin) to FMN and FAD. The current study has extended those findings and has shown that the previously prescribed mineral deficiencies, are accompanied by an expected deficiency in functional vitamin B2. This deficiency then affects the metabolism of fatty acids, glucose and amino acids. Functional B2 deficiency also affects the activity of succinate dehydrogenase – the linking enzyme between energy production in Krebs cycle and electron transfer in the Electron Transport Chain. In addition, functional B2 (as FMN) is also required for the activation of vitamin B6. Given that it is known that vitamin B2, in its active forms, FMN and FAD, is involved as a co-factor in over 100 enzymes, these findings have profound implications for energy production in the brain of the children and for the activation and control of neurotransmitters, amongst other reactions.

The observed deficiency in activation of vitamin B2, is accompanied by a reduced ability to burn fat for energy, and so may explain the observed higher rate of obesity in persons with autism [5-11], and the higher rate of obesity in mothers of children with autism [15-17]. Functional vitamin B2 deficiency, also affects the ability of the enzyme pyruvate dehydrogenase to process pyruvate, which effectively blocks the glycolysis pathway leading to elevated lactic acid. Persons with mutations in the pyruvate dehydrogenase enzyme have been shown to have very elevated lactic acid and neurodevelopmental delay is a universal finding in these individuals [18]. Elevated

lactic acid is one of the features of diabetes, lack of activity of pyruvate dehydrogenase may explain the higher rate of diabetes seen in persons with autism [19, 20] as well as the known association of gestational diabetes in mothers and the subsequent development of autism in the children [21-28]. The reduced ability to produce energy from glucose, the preferred energy source in the brain, would in turn necessitate the catabolism of protein to form ketogenic amino acids, and would explain the elevated levels of glutaric acid and oxalic acid observed in these individuals.

More importantly, the measured association of deficiencies of Iodine, Selenium and/or Molybdenum and functional B2 deficiency in those with autism also provides a potential mode of prevention and treatment of autism. In addition, the same approach has potential application to weight loss in obesity and glucose reduction in diabetes. In separate studies, not reported here, we have examined the levels of functional vitamin B12, using Urinary Organic Acids Tests, and in these studies, every child who was found to be functionally deficient in vitamin B2 was also functionally deficient in vitamin B12. In this regard it has been known for over 40 years that vitamin B12 deficiency in the neonate is associated with developmental delay in children [29-34]. This then poses the theory that the dramatic increase in the rate of autism over the past 20 years could be due to decreases in the intake of Iodine, Selenium and/or Molybdenum in countries, in which soil deficiencies are now more common. Hence lack of one single nutrient could be the precipitating event that results in the spectrum of developmental delays such as those seen in Autism Spectrum Disorder.

5. Conclusions

Dietary deficiency of Iodine, Selenium and/or Molybdenum in children with autism, results in insufficient activation of dietary vitamin B2. This then leads to a functional deficiency in vitamin B2, thereby resulting in reduced capacity of the child to gain energy from the metabolism of fats, sugar and protein. In addition, functional B2 is an essential requirement for the metabolism of vitamin B12, and hence a deficiency in functional vitamin B2 would potentially lead to the accumulation of inactive vitamin B12, in these individuals, a known predisposing factor for developmental delay.

Acknowledgements

Acknowledgements go to all of those parents who have contributed their data to the preparation of this manuscript in the hope that the manuscript will be of benefit to those who have children with autism.

Compliance with Ethical Standards

- We declare that there are no potential conflicts of interest.
- Research did not involve human participants and/or animals.
- No Informed consent is required, all data is “blinded” and as such is anonymous.
